Tank container

Westerwälder Eisenwerk Gerhard GmbH

Inventor(s): Gerhard, Helmut

Application No. EP88104122 EP, Filed 19880315, A2 Published 19881005, A3 Published 19881214
Granted 19911113

Abstract:

In a tank container, the tank (16) which is formed of a plurality of parallel cylindrical shells (17, 18) is connected by saddle structures (19) to a pair of end frames (10). The saddle structures (19) each consist of a U-bar (20) having its legs welded to the respective shell (17, 18) and two L-bars (21, 22) welded to the lower traverse (13) and, respectively, the corresponding corner upright (11, 12).

Detailed Description

The invention relates to a tank container of the type set forth in the preamble part of claim 1.

A tank container of this type is known from US-A-4,593,832. There, the tank which has its envelope formed of a plurality of part-cylindrical shells is connected to end frames by means of saddle structures each of which comprises an end ring welded to the tank head and a saddle ring fixed to diagonal struts of the respective end frame. During assembly, the two rings may be displaced with respect to each other to compensate lengthwise tolerances and are subsequently welded together.

In case of very high accelerations along the tank axis, as occur in severe buffing tests, the tank may undergo permanent deformation because the diagonal distance between the lower corner fitting and the nearest connecting point at the diagonal strut of the end frame results in excessive torque.

With a tank the envelope of which is formed of a plurality of adjacent part-cylindrical shells in order optimally to utilize the volume defined by the end frames, there is insufficient space for lower diagonal supports known from US-A-4,603,788, which form additional supports for a tank otherwise mounted by end saddles and introduce the forces immediately into the lower corner fittings.

It is the object of the invention at least partly to overcome disadvantages as occur with comparable prior art tank containers. A more specific object of the invention may be seen to reside in providing a saddle support for a tank container of the type initially referred to, which permits introducing axial forces into the lower corner fittings along a straight line and over a distance that is as short as possible and which, at the same time, consists of a small number of readily manufactured parts permitting simple assembly.

The solution to this object according to the invention is set forth in the characterizing part of claim 1. The saddle structures thus provided may each consist, in their simplest form, of one U-bar and two L- or angle bars, i.e. of inexpensive, commercially available profiled material. During assembly, the two L-bars may be moved relative to the U-bar welded to the tank both in the longitudinal direction and transversely

thereto so that tolerances may be compensated. The final welding of the L-bars to the end frame and U-bar is done in a state in which all parts are positioned relatively to each other so as to result in the desired configuration. A dimensionally accurate assemblage of a pre-fabricated tank with pre-fabricated end frames is thus facilitated by moving and subsequently welding light-weight structural parts without much labour or corrective and adaptive flame cutting or forming.

When the tank envelope is formed of a plurality of parallel part- cylindrical shells, the corner region which exists between the tank envelope and the end frame and is about triangular if viewed in the axial direction has a comparatively small area. Therefore, the U-bar is close to the corner fitting with relatively short legs so that the forces which the tank applies to the U-bar are transmitted to the end frame in the close vicinity of the corner fitting via the L-bars connected to the U- bar.

DE-A-1 937 192 discloses a tank container which is mounted by brackets provided in the two lower corners. These brackets, however, are structures of complicated shape which must be adapted not only to the tank but also to the space existing between the tank and the frame and therefore do not permit the compensation of tolerances. Moreover, they require a framework with a complete base structure and thus do not allow a mere end-side mounting (^) of the tank to end frames.

The developments of the invention according to claims 2 to 4 result in an advantageous fixation and stiffening of the U-bar relative to the tank. The arrangement of claim 4 is particularly useful to avoid peak stresses. In the development of the invention according to claim 5, the L-bars serve not only to fix the U-bar with respect to the end frame but also to stiffen the L-bar itself.

Further reinforcing measures are characterized in claims 6 and 7, the arrangement of claim 6 being particularly useful in permitting that rigid grappler arm lifting areas as regularly required on land tank containers and tanks for changing transport forms are provided without additional expense or extra weight.

Claims 8 and 9 relate to different ways of mounting (^) the L-bars, depending on the space available and the shape of the U-bar.

The development of the invention according to claim 10 results in the advantage that commercially available isosceles angled profiles may be used for the L-bars.

Embodiments of the invention will now be explained with reference to the drawings, in which

- Figure 1 is an end view of a tank container,
- Figure 2 is an enlarged view of the left-hand lower corner region of the tank container of Figure 1,
- Figure 3 is a lateral view of the right-hand lower corner region, as viewed in the direction of the arrow III in Figure 1, and
- Figure 4 is a view similar to Figure 2 showing a modified embodiment.

The end frame 10 of the tank container shown in Figure 1 consists of two corner uprights 11, 12 and two traverses 13, 14 interconnected by corner fittings 15. The tank 16 is connected to the end frame 10 by two saddle structures generally designated 19 in Figure 1.

The tank 16 includes an envelope formed of two part-circular cylindrical shells 17, 18, the axes of the two cylinders extending parallel to each other in a common horizontal plane. Alternatively, the tank envelope may be formed of three part-circular cylindrical shells with parallel axes contained in one horizontal plane.

Tank containers having envelopes of this type are known e.g. from US-A-3,799,383. In a further modification for which the saddle- type mounting (^) described below is suitable, the tank envelope is formed of four parallel part-circular cylindrical shells the axes of which define in a transverse plane the four corners of a rectangle. A tank container with such a tank is known from US-A-4,593,832. In all these tanks in which the envelope is made of a plurality of part-cylindrical shells, the approximately triangular region defined in Figure 1 by the lower traverse 13, the left-hand or right-hand corner upright 11, 12 and the projection of the respective shell 16, 17, is relatively small as compared to a tank container having a full-circular cylindrical tank (^) envelope.

Each of the two saddle structures 19 according to Figures 1 to 3 includes a U-bar 20 having the edges of its legs 24 welded to the respective shell 17, 18 and two L-bars 21, 22 having the edges of both of their legs welded to the upper surface of the lower traverse 13 and, respectively, the inner surface of the corresponding corner upright 11, 12. An outer surface of each L-bar 21, 22 is welded to the outer surface of the web 23 of the U- bar 20.

In the embodiment of Figures 1 to 3, the U- bar 20 has a comparatively wide web 23 and comparatively short legs 22. This on the one hand results in sufficient contacting surfaces between the web 23 of the U-bar 20 and the respective leg of the L-bars 21, 22, and on the other hand leaves sufficient cross-sectional area in which the L-bars may be readily inserted.

Upon assembly, the tank 16 with the U-bars 20 welded thereto is brought into the desired alignment with respect to the end frame 10 whereupon the L-bars 20, 21 are inserted and moved horizontally along the traverse 13 and, respectively, vertically along the upright 11, 12 until they contact the outer surface of the web 23 of the U-bar 20. Subsequently, the edges of the legs of the L-bars 21, 22 are welded to the inner surfaces of the traverse 13 or upright 11, 12, respectively. Until the L-bars 21, 22 are welded to the U-bar 20, lengthwise tolerances that may exist between the tank 16 and the end frame 10 may be compensated by shifting the tank in the axial direction.

As appears from Figure 3, the L-bars 21, 22 extend in the axial direction of the tank beyond the axial width of the traverse 13 and uprights 11, 12. Also, the U-bar 20 welded to the respective tank shell 17, 18 extends beyond the tank envelope and terminates short of the outer end surface of the end frame 10. Sufficient length for interconnecting the three bars 20, 21 and 22 is thus made available.

At the other end, the U-bar 20 terminates at a reinforcing member 25 extending in the circumferential direction of the tank 16, the member 25 in the embodiment of Figure 3 having an L-shaped cross-section and terminating in low-stress rounded portions 26. Alternatively, the U-bar may terminate at a reinforcing ring which completely surrounds the tank envelope.

As further shown in Figure 3, the end of the U-bar 20 facing the end frame 10 is supported by the tank head 27 by two junction plates 28 which are fitted between the legs 24 of the U-bar 20 and the outer surface of the tank head 27, the free edges of the junction plates 28 extending in an inclined or curved manner from the outer end of the U-bar 20 to the tank head 27.

As further indicated in Figures 2 and 3, the two junction plates 28 have their ends bent towards each other to result in a continuous weld on the tank head 27. Peak stresses are thus avoided which are otherwise liable to occur at the free ends of welds of force transmitting members.

Figure 3 also shows a generally rectangular junction plate 29 connected to the upright 12 which according to Figure 2 has its upper edge bent inwardly to form a grapple arm lifting area 30 and serves

as a guide when engaged by grappler arms. According to Figure 2, the grappler arm lifting area 30 is also connected by a further inclined junction plate 31 to the diagonally downwardly and outwardly extending leg of the L-bar 22, which results in an essential stiffening of both the grappler arm lifting area 30 and the L-bar 22 itself.

It is further indicated in Figure 2 that the diagonally downwardly and outwardly extending leg of the L-bar 21 welded to the traverse 13 may be extended by a junction plate 32 the lower edge of which is inclined inwardly in the longitudinal direction of the tank. The L-bar 21 may thus be stiffened in similar way as the L-bar 22 by means of the junction plate 31. In both cases, the junction plates 31 and 32 are advantageously welded to the vertical inner surface of the upright 11, 12 and traverse 13, respectively.

As assumed in Figure 2, the U-bar 20 is welded to the tank shell 17, 18 in such a manner that its web 23 and legs 24 extend at an angle of 45° with respect to the horizontal and vertical. In this case, isosceles L-bars 21, 22 are used, but the leg width may be different for the two L-bars 11, 12 as shown in Figure 1.

The modified embodiment shown in Figure 4 differs from that of Figure 2 in that the two L-bars 21, 22 abut the legs 24 rather than the web 23 of the U-bar 20. In this case, the width of the web 23 of the U-bar 20 is reduced whereas the height of its legs 24 is increased. Such a shape may be preferred depending on the position of the tank shells 17, 18 relative to the end frame 10.

In either case, the forces exerted by the tank 16 are transmitted via the U-bar 20 and the L-bars 21, 22 connected therewith to the end frame 10 at a location that is immediately adjacent the respective corner fitting 15. In other words, the lever arm effective between the location where the load is transmitted from the tank and the corner fitting which transmits this load to the corresponding vehicle or other supporting system is relatively short which results in a correspondingly small torque even under high axial acceleration.

Depending on the size of the tank container and the load to be transmitted, the saddle structures 19 described above may be provided as the sole connecting elements between the tank 16 and end frames 10 or in addition to other connecting elements provided in the upper frame area.

Claims (English)

1. A tank container comprising a tank (16) having an envelope formed of a plurality of cylindrical shells (17, 18), two end frames (10) each of which includes two corner uprights (11, 12) and two traverses (13, 14), and saddle structures (19) connecting the tank (16) to the end frames (10), characterized in that each saddle structure (19) comprises: a U-bar (20) extending parallel to the axis of the tank and having the edges of its two legs (24) fixed to the respective shell (17, 18) in such a way that its web (23) is inclined, and two L-bars (21, 22) having the edges of both of their legs fixed to the inner surfaces of the respective corner upright (11, 12) or lower traverse (13), one of the legs being welded to the respective parallel surface portion (23, 24) of the U-bar (20).
2. The tank container of claim 1, characterized in that the end edge of the U-bar (20) facing away from the end frame (10) is welded to a reinforcing member (25) extending in the circumferential direction of the tank (10).
3. The tank container of claim 1 or 2, characterized in that the end of the U-bar (20) facing the end frame (10) is supported by junction plates (28) fitted between the legs (24) of the U-bar (20) and the tank head (27).
4. The tank container of claim 3, characterized in that the ends of the junction plates (28) are bent

- towards each other to form a continuous weld on the tank head (27).
5. The tank container of any one of claims 1 to 4, characterized in that the L-bars (21, 22) extend beyond the axial width of the end frame (10) in the direction of the tank (16).
 6. The tank container of claim 5, characterized in that the L-bar (22) fixed to the corner upright (11, 12) is connected to a junction plate (29) forming a grapple edge (30).
 7. The tank container of claim 5 or 6, characterized in that at least one leg of at least one L-bar (21, 22) is connected to a junction plate (31, 32) fixed to the inner surface of the end frame (10) facing the tank (16).
 8. The tank container of any one of claims 1 to 7, characterized in that the L-bars (21, 22) contact the web (23) of the U-bar (20).
 9. The tank container of any one of claims 1 to 7, characterized in that the L-bars (21, 22) contact the legs (24) of the U-bar (20).
 10. The tank container of any one of claims 1 to 9, characterized in that the web (23) of the U-bar (20) extends at an angle of substantially 45° with respect to the corner upright (11, 12) and traverse (13) of the end frame (10).

Claims (French)

1. Conteneur-citerne comportant une citerne (16) possédant une enveloppe constituée d'une pluralité de coquilles cylindriques (17,18), deux cadres terminaux (10) dont chacun comprend deux montants d'angle (11,12) et deux traverses (13, 14), et des structures formant berceau (19) reliant la citerne (16) aux cadres terminaux (10), caractérisé en ce que chaque structure formant berceau (19) comporte: une barre en U (20) s'étendant parallèlement à l'axe de la citerne et ayant les bords de ses deux branches (24) fixés à la coquille respective (17,18) de telle manière que son âme (23) soit inclinée, et deux barres en L (21,22) ayant les bords de leurs deux branches fixés aux surfaces intérieures du montant d'angle respectif (11,12) ou de la traverse inférieure (13), une des branches étant soudée à la partie de surface parallèle respective (23,24) de la barre en U (20).
2. Conteneur-citerne selon la revendication 1, caractérisé en ce que le bord terminal de la barre en U (20) éloigné du cadre terminal (10) est soudé à un élément de renfort (25) s'étendant dans le sens circonférentiel de la citerne (16).
3. Conteneur-citerne selon la revendication 1 ou 2, caractérisé en ce que l'extrémité de la barre en U (20) tournée vers le cadre terminal (10) est supportée par des plaques de liaison (28) ajustées entre les branches (24) de la barre en U (20) et l'avant de la citerne (27).
4. Conteneur-citerne selon la revendication 3, caractérisé en ce que les extrémités des plaques de liaison (28) sont courbées l'une vers l'autre pour former une soudure continue sur l'avant de la citerne (27).
5. Conteneur-citerne selon l'une quelconque des revendications 1 à 4, caractérisé en ce que les barres en L (21,22) s'étendent au delà de la largeur axiale du cadre terminal (10) dans la direction de la citerne (16).
6. Conteneur-citerne selon la revendication 5, caractérisé en ce que la barre en L (22) fixée au montant d'angle (11,12) est reliée à une plaque de liaison (29) formant un bord de levage (30).
7. Conteneur-citerne selon la revendication 5 ou 6, caractérisé en ce qu'au moins une branche d'au moins une barre en L (21,22) est reliée à une plaque de liaison (31, 32) fixée à la surface intérieure du cadre terminal (10) tournée vers la citerne (16).
8. Conteneur-citerne selon l'une quelconque des revendications 1 à 7, caractérisé en ce que les barres en L (21,22) sont en contact avec l'âme (23) de la barre en U (20).
9. Conteneur-citerne selon l'une quelconque des revendications 1 à 7, caractérisé en ce que les barres en L (21,22) sont en contact avec les branches (24) de la barre en U (20).
